

## Multiple Choice

1. **Answer:** A

*Options:* A) group polarization; B) deindividuation; C) group escalation; D) conformity pressure; E) groupthink

*Note:* Group polarization is the psychological phenomenon in which discussions within a like-minded group lead to the enhancement of the group's prevailing attitudes, resulting in more extreme positions than those held by individual members prior to group interaction.

2. **Answer:** E

*Options:* A) 25; B) 90; C) 75; D) 68; E) 95

*Note:* The correct answer is 95 percent because the WISC (Wechsler Intelligence Scale for Children) is designed to have a normal distribution of intelligence scores, where approximately 95 percent of the population falls within two standard deviations (typically between 70 and 130) of the mean score of 100.

3. **Answer:** A

*Options:* A) transduce sound waves to stimulate the ossicles; B) amplify sound waves before they reach the eardrum; C) conduct sound by exciting the cilia in the inner ear; D) control the balance and coordination of the body; E) produce earwax to protect the ear canal

*Note:* The outer ear functions by collecting sound waves and funneling them into the ear canal, where they cause the eardrum to vibrate, ultimately leading to the stimulation of the ossicles in the middle ear, thereby facilitating the transduction of sound energy into mechanical energy.

4. **Answer:** A

*Options:* A) performance review; B) job analysis; C) job description; D) organizational analysis; E) workforce analysis

*Note:* A performance review systematically assesses an employee's work performance and contributions, providing essential insights into job requirements and standards that inform compensation decisions.

5. **Answer:** A

*Options:* A) frequency theory; B) dual-process theory; C) specificity theory; D) trichromatic; E) gestalt theory

*Note:* The frequency theory posits that the perception of pitch is determined by the specific location along the basilar membrane that vibrates in response to sound waves, with different frequencies producing peak vibrations at distinct places along the membrane.

## True / False

6. **Answer:** False

*Options:* A) True; B) False

*Note:* Test validity encompasses both the authenticity of the test content and its accuracy in measuring what it is intended to measure, making the statement false.

7. **Answer:** False

*Options:* A) True; B) False

*Note:* While high blood pressure is a risk factor for heart disease, studies indicate that other factors, such as stress, hostility, and competitiveness associated with Type A behavior, play a more significant role in its development.

8. **Answer:** True

*Options:* A) True; B) False

*Note:* Self-reinforcement plays a crucial role in Bandura's social learning theory because it allows individuals to internally reward themselves for their actions, thereby sustaining motivation and reinforcing behaviors even when external rewards are not present.

9. **Answer:** False

*Options:* A) True; B) False

*Note:* The statement is false because clapping hands is a simpler gross motor skill that typically develops before the more complex fine motor skill of tying shoes, which requires greater dexterity and coordination.

10. **Answer:** True

*Options:* A) True; B) False

*Note:* Research into frustration has revealed that negative emotional states can paradoxically enhance motivation and reward-seeking behavior, thereby deepening our understanding of behavioral responses in psychology.

## Long Form Response

11. **Answer:** Berkowitz's revision of the frustration-aggression hypothesis emphasizes the significant role of environmental cues in the expression of aggression following frustration. He posits that frustration alone does not automatically lead to aggressive behavior; rather, the presence of aggressive cues in the environment can trigger such responses. For example, exposure to weapons or aggressive symbols can heighten the likelihood of aggression in individuals who are already frustrated, suggesting that situational factors play a critical role in the activation of aggressive impulses. This nuanced understanding highlights the interplay between individual emotional states and contextual triggers, making it clear that aggression is not solely a product of frustration but is influenced by the surrounding environment. Thus, Berkowitz's revision underscores the importance of considering both internal and external factors in the study of aggressive behavior.

*Note:* correct because it accurately reflects Berkowitz's view that while frustration can increase the potential for aggression, it is the environmental cues, such as aggressive symbols or weapons, that actualize this aggression in individuals.

12. **Answer:** Crowding can significantly impact psychological well-being, often leading to heightened stress levels. Research indicates that men may experience less stress than women in crowded conditions due to differences in coping mechanisms and socialization. Men are generally socialized to adopt a more resilient and less emotionally expressive approach to stress, which may enable them to better manage uncomfortable situations like crowding. Additionally, physiological responses to stress, such as hormonal fluctuations, may differ by gender, with women often exhibiting a stronger stress response due to higher levels of oxytocin and a tendency towards communal coping strategies. Consequently, these factors contribute to the observed gender disparity in stress levels associated with crowded environments.

*Note:* The answer correctly highlights that crowding increases psychological stress and emphasizes gender differences in coping mechanisms and socialization, suggesting that men's resilience and less emotional expressiveness may contribute to their lower stress levels in crowded environments compared to women.
