

Multiple Choice

1. **Answer:** A

Options: A) autonomy vs. shame and guilt; B) integrity vs. despair; C) identity vs. role confusion; D) empathy vs. apathy; E) initiative vs. guilt

Note: The correct answer is "autonomy vs. shame and guilt" because Erikson's theory of psychosocial development identifies this stage as crucial for young adults, where they must achieve a balance between developing a sense of independence and the potential feelings of inadequacy that can arise from dependence on others.

2. **Answer:** A

Options: A) behaviorists; B) psychoanalysts; C) developmental psychologists; D) neuropsychologists; E) humanists

Note: The focus of structuralists on observable behaviors and the analysis of mental processes aligns closely with behaviorists' emphasis on studying behavior through measurable and objective methods, thus connecting their approaches in psychology.

3. **Answer:** A

Options: A) parietal lobe is to frontal lobe."; B) temporal lobe is to parietal lobe."; C) temporal lobe is to frontal lobe."; D) occipital lobe is to parietal lobe."; E) parietal lobe is to occipital lobe."

Note: The correct answer is based on the analogy that both vision and hearing are sensory modalities processed by different areas of the brain, with the parietal lobe primarily associated with sensory integration, including vision, and the frontal lobe involved in higher cognitive functions and decision-making, thereby highlighting the distinct yet complementary roles of these brain regions in processing sensory information.

4. **Answer:** A

Options: A) rationality versus irrationality; B) stability versus change; C) cognition versus behavior; D) qualitative versus quantitative data; E) conscious versus unconscious influences

Note: The correct answer is rationality versus irrationality because the debate over whether development occurs in stages often involves examining the cognitive processes that underpin rational decision-making during different developmental phases, highlighting how reasoning can evolve or manifest differently across stages.

5. **Answer:** A

Options: A) Large-group programs emphasizing development of children's self-esteem; B) Mandatory health screenings for all students; C) School-wide campaigns promoting healthy eating habits; D) Small-group counseling of students affected by initial stages of divorce; E) Regular teacher-parent meetings to discuss student progress

Note: Large-group programs emphasizing the development of children's self-esteem

represent tertiary prevention in a school setting because they focus on enhancing psychological well-being and resilience, thereby addressing issues that may arise from previous mental health challenges or adverse experiences.

True / False

6. **Answer:** True

Options: A) True; B) False

Note: In Pavlov's experiments, the small bit of meat powder is considered an unconditioned stimulus (US) because it inherently triggers a natural, reflexive response (salivation) without any prior conditioning.

7. **Answer:** False

Options: A) True; B) False

Note: The statement is false because sweet lemons rationalization refers to the psychological defense mechanism where individuals perceive a negative situation as more favorable to cope with disappointment, which correctly describes the concept rather than misrepresenting it.

8. **Answer:** False

Options: A) True; B) False

Note: Intelligence researchers typically emphasize the importance of core subjects such as math and science in fostering cognitive development, often viewing nonessential subjects like art and music as secondary to academic achievement.

9. **Answer:** False

Options: A) True; B) False

Note: Intermittent reinforcement can lead to the persistence of a behavior but does not necessarily strengthen the conditioned response as consistently as continuous reinforcement, which is more effective in establishing and enhancing the initial learning of the behavior.

10. **Answer:** True

Options: A) True; B) False

Note: This statement is true because Elisabeth Kübler-Ross's model of grief identifies denial as the first stage of the emotional response to terminal illness, where patients may react with disbelief or shock at their diagnosis.

Long Form Response

11. **Answer:** Separation anxiety is a normal developmental phase in infants typically occurring between 6 and 12 months, characterized by distress experienced when a caregiver departs. This phenomenon is significant as it reflects the infant's attachment to their primary caregiver, underscoring the development of secure attachments as essential for emotional and social growth. According to attachment theory, the intensity

of separation anxiety is indicative of the quality of the infant-caregiver bond; a secure attachment fosters resilience and confidence, whereas insecure attachments can lead to anxiety and behavioral issues later in life. Understanding separation anxiety not only highlights its role in the formation of attachment relationships but also emphasizes the need for responsive caregiving to support healthy emotional development.

Note: The answer correctly identifies separation anxiety as a normal developmental phase that signifies the infant's attachment to their caregiver, linking this phenomenon to attachment theory and emphasizing its importance for emotional and social development.

12. **Answer:** Carl Rogers would interpret Peter's parents' reaction to his decision to become an artist as a significant threat to their self-structure, which is shaped by their belief that a male family member must pursue a prestigious career, such as medicine, to be deemed valuable. This belief creates a dissonance between their familial values and their love for Peter, leading to emotional distress as they struggle to reconcile their expectations with his aspirations. The incongruence between their values and Peter's choice may cause them to experience anxiety and disappointment, reflecting their internal conflict. Ultimately, their reaction highlights the impact of societal norms on familial relationships and the importance of self-acceptance in fostering genuine support for individual choices.

Note: The answer accurately reflects Carl Rogers' concepts of self-structure and incongruence, illustrating how Peter's parents' rigid beliefs about masculinity and career success conflict with their emotional bond to him, leading to internal distress and highlighting the impact of familial values on individual identity.
