

Multiple Choice

1. **Answer:** C

Options: A) use the process of elimination to answer multiple-choice questions.; B) interpret visual cues.; C) read a map.; D) perform mathematical calculations.; E) write a coherent sentence.

Note: Unilateral damage to the left hemisphere typically affects language processing and verbal skills, while spatial abilities, such as reading a map, are more associated with the right hemisphere, making the inability to read a map less likely.

2. **Answer:** D

Options: A) psychological term for an uncontrollable state of mind.; B) medical term for a severe mental illness.; C) popular (lay) term for a severe mental illness.; D) legal, non-psychiatric term for certain types of mental disorders.; E) legal, non-psychiatric term for a psychotic disorder with an unknown etiology.

Note: The term "insanity" is primarily used in legal contexts to determine an individual's mental state during the commission of a crime, rather than as a clinical diagnosis in psychiatry.

3. **Answer:** A

Options: A) Stage 4 sleep; B) Stage 1 sleep; C) REM sleep; D) Stage 3 sleep; E) Deep sleep

Note: Alpha waves are most closely associated with relaxed wakefulness and light sleep, but they are not predominant in Stage 4 sleep, which is characterized by delta waves; therefore, the correct answer should actually reflect that alpha waves are more linked to stages of relaxed consciousness rather than deep sleep.

4. **Answer:** A

Options: A) The school must invest in more modern educational technology.; B) Students who are not meeting competencies must be placed in lower grade levels.; C) Students must be given more time to develop competencies.; D) The school must hire more teachers to reduce class size.; E) Parents of students not meeting competencies must be contacted for meetings.

Note: Investing in more modern educational technology can enhance instructional methods and provide personalized learning experiences, thereby addressing the identified gaps in student performance and helping to meet school competencies.

5. **Answer:** A

Options: A) reinforcement; B) an unconditioned stimulus; C) conditioned response; D) operant conditioning; E) generalization

Note: The correct answer is reinforcement because, in classical conditioning, the association between the tone (conditioned stimulus) and the salivation response (conditioned

response) indicates that the dogs have learned to associate the tone with food, demonstrating the role of reinforcement in strengthening this learned behavior.

True / False

6. **Answer:** False

Options: A) True; B) False

Note: Simultaneous presentation of the conditioned and unconditioned stimuli often leads to weaker conditioning compared to methods like delayed or trace conditioning, where the conditioned stimulus precedes the unconditioned stimulus, allowing for better association formation.

7. **Answer:** True

Options: A) True; B) False

Note: Empirical literature indicates that mothers tend to possess a strong emotional and cognitive investment in their children's development, leading to more accurate recollections of milestones such as motor development and weight gain.

8. **Answer:** False

Options: A) True; B) False

Note: Social ostracism is not the primary factor influencing learning in people with antisocial personalities; rather, their learning is more significantly affected by a range of factors including environmental influences, cognitive deficits, and a lack of empathy.

9. **Answer:** True

Options: A) True; B) False

Note: The triarchic theory of intelligence, proposed by Robert Sternberg, primarily categorizes intelligence into analytical, creative, and practical components rather than providing a developmental framework for understanding how intelligence evolves throughout different stages of life.

10. **Answer:** False

Options: A) True; B) False

Note: Motivation and arousal are interconnected processes in psychology, as arousal often serves as a physiological response that energizes and directs behavior toward achieving motivated goals, indicating that one influences the other.

Long Form Response

11. **Answer:** Proactive and retroactive interference are key concepts that illustrate the complexities of information classification and retrieval in cognitive psychology. Proactive interference occurs when previously learned information disrupts the acquisition and recall of new information, making it difficult to learn or remember new material. Conversely, retroactive interference happens when newly learned information interferes with the retrieval of older memories, often leading to the forgetting of past knowledge.

These phenomena underscore the dynamic nature of memory, highlighting how the interplay between old and new information can complicate cognitive processes. Understanding these interferences is crucial for developing effective strategies for memory enhancement and retrieval, as they reveal the intricate mechanisms by which information is organized and accessed within the mind.

Note: correct because it accurately defines proactive and retroactive interference, demonstrating how both types of interference complicate the processes of memory classification and retrieval in cognitive psychology.

12. **Answer:** Mood significantly influences information processing through the central route in the elaboration likelihood model (ELM). When an individual is in a neutral or slightly negative mood, they may be more motivated to engage in careful scrutiny of persuasive messages, leading to deeper cognitive processing. This heightened scrutiny can result in more thoughtful evaluation of arguments and evidence, ultimately affecting the likelihood of attitude change. Consequently, persuasive communication strategies should consider the target audience's mood; messages that are more complex or require critical thinking are likely to be more effective when the audience is in a neutral or slightly negative emotional state. Understanding this relationship underscores the importance of tailoring persuasive efforts to align with the emotional context of the audience.

Note: correct because it accurately describes how varying moods can alter an individual's motivation and ability to process persuasive messages through the central route, ultimately impacting the effectiveness of attitude change in persuasive communication.
