

Multiple Choice

1. **Answer:** A

Options: A) Dysphagia; B) Aphasia; C) Dysphonia; D) Dyspraxia; E) Dyslexia

Note: The correct answer is Dysphagia because it is associated with difficulties in the physical act of swallowing and does not pertain to the regulation of speech characteristics such as rate, rhythm, pitch, and loudness, which are more accurately described by terms like dysarthria or speech sound disorders.

2. **Answer:** A

Options: A) Texture; B) Location; C) Popular; D) Shape; E) Orientation

Note: The Exner Scoring System for the Rorschach Inkblot Test includes categories such as form, color, and movement, but does not include texture as a scoring criterion.

3. **Answer:** C

Options: A) are more likely to seek group counseling than individual counseling; B) remain in counseling for approximately the same length of time as nonminority clients; C) terminate counseling significantly earlier than do non-minority clients; D) seek counseling services at the same rate as non-minority clients

Note: Research indicates that minority group members often face unique cultural, socioeconomic, and systemic barriers that can lead to a lack of trust in the counseling process, resulting in earlier termination of therapy compared to non-minority clients.

4. **Answer:** A

Options: A) gender identity; B) gender neutrality; C) gender assimilation; D) gender fluidity; E) gender affirmation

Note: Kohlberg's cognitive-developmental theory posits that gender identity is the first stage in gender-role acquisition, where children begin to recognize and label themselves and others as male or female, laying the foundation for further understanding of gender roles.

5. **Answer:** C

Options: A) Conformity, association, and adaptation; B) Agreement, alliance, and absorption; C) Compliance, identification, and internalization; D) Submission, emulation, and inculcation; E) Adherence, affiliation, and incorporation

Note: The correct answer is Compliance, identification, and internalization because these terms represent distinct levels of response to social influence, with compliance driven by external rewards or punishments, identification rooted in the desire to be associated with a group, and internalization reflecting a deeper acceptance of beliefs and values.

True / False

6. **Answer:** False

Options: A) True; B) False

Note: Low levels of melatonin are primarily associated with sleep disturbances rather than anxiety symptoms, as melatonin's main role is to regulate sleep-wake cycles rather than directly influence anxiety levels.

7. **Answer:** False

Options: A) True; B) False

Note: The spinal cord is primarily responsible for transmitting signals between the brain and the body, while memory storage and complex cognitive functions are primarily managed by various regions of the brain, particularly the hippocampus and the cerebral cortex.

8. **Answer:** False

Options: A) True; B) False

Note: The frontal lobe is located at the front of the brain and is not considered to be at the most central or protected part, which is typically associated with the brainstem and other deeper structures responsible for basic life functions.

9. **Answer:** True

Options: A) True; B) False

Note: Schizophrenia and manic-depressive psychosis, also known as bipolar disorder, are prevalent diagnoses in clinical settings due to their significant impact on individuals' mental functioning and the frequency with which they present in psychiatric practice.

10. **Answer:** False

Options: A) True; B) False

Note: Hersey and Blanchard's situational leadership model actually recommends a directive style for subordinates with low ability and high motivation, as they require guidance to develop their skills.

Long Form Response

11. **Answer:** Castration significantly alters sexual behavior in animals, with varying effects observed across species. In highly developed primates, such as humans, castration does not hinder the ability to engage in sexual acts, provided the male is sexually mature and has prior sexual experience. This phenomenon suggests that the psychological and learned components of sexuality may outweigh purely hormonal influences in these advanced species. In contrast, less developed animals often exhibit marked reductions in sexual behavior post-castration, highlighting the critical role of testosterone in their reproductive functions. Understanding these differences enhances our comprehension of human sexuality, suggesting a complex interplay of biological, psychological, and social factors that shape sexual expression and behavior.

Note: The answer correctly highlights the differential impact of castration on sexual behavior in highly developed primates versus less developed animals, emphasizing the importance of psychological and learned experiences in shaping sexuality beyond hormonal influences.

12. **Answer:** The Gestalt organizing principle of proximity significantly influences our interpretation of ambiguous visual stimuli, as it dictates how we group elements based on their spatial relationships. In the example of the phrase "i n car n a t e," the proximity of the letters creates a visual ambiguity, leading viewers to perceive "inn" and "carnate" as distinct clusters rather than a single, continuous word. This demonstrates that our cognitive processing favors grouping letters that are close together, which can lead to misinterpretations or alternative readings. Thus, the principle of proximity illustrates how our perceptual organization can shape our understanding of visual information, particularly in contexts where clarity is compromised. This phenomenon highlights the interplay between visual perception and cognitive processing in interpreting ambiguous stimuli.

Note: correct because it illustrates how the Gestalt principle of proximity affects our visual perception by causing us to group letters based on their spatial arrangement, resulting in the interpretation of "i n car n a t e" as two separate clusters rather than one continuous word.
