

Multiple Choice

1. **Answer:** A

Options: A) Perls.; B) Maslow.; C) Erikson.; D) Piaget.; E) Rogers.

Note: The correct answer is Perls because his Gestalt therapy emphasizes the importance of interpersonal relationships and personal fulfillment through the integration of friendship, occupation, and love as essential life tasks for psychological well-being.

2. **Answer:** C

Options: A) too little curvature of the cornea and lens; B) too much curvature of the retina and lens; C) too much curvature of the cornea and lens; D) too much curvature of the iris and cornea; E) incorrect alignment of the cornea and retina

Note: Nearsightedness, or myopia, occurs when the eyeball is too long or the cornea and lens have excessive curvature, causing light rays to focus in front of the retina instead of directly on it.

3. **Answer:** A

Options: A) implementation of the intervention by the researcher; B) pre-determined assignment of participants to groups; C) use of a non-comparison group; D) use of multiple measures of outcome; E) use of a single group of participants

Note: Quasi-experimental designs lack random assignment and are characterized by the implementation of the intervention without direct control by the researcher, distinguishing them from true experimental designs where the researcher actively manipulates the independent variable.

4. **Answer:** A

Options: A) Triarchic theory of intelligence; B) Multiple intelligences theory; C) Cognitive development theory; D) The positive manifold; E) G theory

Note: The triarchic theory of intelligence, proposed by Robert Sternberg, focuses on analytical, creative, and practical aspects of intelligence rather than developmental processes, making it less relevant to developmental models of intelligence.

5. **Answer:** B

Options: A) cell body; B) myelin; C) synaptic vesicles; D) glial cells; E) terminal buttons

Note: Myelin is crucial in the electrical aspect of neural transmission because it forms a protective insulating layer around axons, which facilitates the rapid propagation of electrical impulses through saltatory conduction.

True / False

6. **Answer:** True

Options: A) True; B) False

Note: The statement is true because neurotic individuals often cling to maladaptive coping mechanisms and symptoms, believing that persistence will eventually lead to anxiety relief, even when those symptoms prove ineffective.

7. **Answer:** False

Options: A) True; B) False

Note: A lesion in the occipital lobe primarily affects visual processing, while facial recognition abilities are primarily associated with the fusiform gyrus located in the temporal lobe.

8. **Answer:** True

Options: A) True; B) False

Note: Lack of exercise contributes to Type A behavior by fostering heightened stress and aggression, which are linked to increased cardiovascular risk factors, thereby elevating the likelihood of heart disease.

9. **Answer:** False

Options: A) True; B) False

Note: The statement is false because Erikson's developmental crisis for young adults is centered around intimacy vs. isolation, not autonomy vs. shame and guilt, which pertains to the earlier stage of development in childhood.

10. **Answer:** False

Options: A) True; B) False

Note: Cognitive dissonance primarily involves the internal psychological conflict that arises when an individual holds contradictory beliefs or attitudes, rather than being primarily linked to external conflicts or social pressures.

Long Form Response

11. **Answer:** Neal Miller proposed that an organism in a conflict situation has several behavioral alternatives that depend on the proximity to a goal and the relative strengths of approach and avoidance drives. When an organism is close to a desired goal, the approach drive typically dominates, leading to behaviors that facilitate reaching that goal. Conversely, if the goal is perceived as being far away or if the avoidance drive is stronger-due to potential negative consequences-the organism may exhibit avoidance behaviors. Additionally, the intensity of these drives influences the likelihood of engaging in certain behaviors; a stronger approach drive in close proximity to the goal can result in persistence, while a stronger avoidance drive can lead to withdrawal or distraction. Thus, the interplay between goal proximity and drive strength crucially shapes the behavioral responses of an organism faced with conflicting motives.

Note: The answer correctly identifies that Neal Miller's theory posits that an organism's behavioral alternatives in conflict situations are influenced by the interplay of goal proximity and the relative strengths of approach and avoidance drives, leading to different behaviors based on these factors.

12. **Answer:** The projective hypothesis in psychology posits that an individual's social functioning can serve as a reflection of their underlying psychological processes. This relationship suggests that the way people interact with others and navigate social situations may reveal their internal thoughts, emotions, and unresolved conflicts. For example, individuals displaying aggression in social contexts might be projecting their own internal struggles or anxieties. Understanding this connection has significant implications, as it emphasizes the importance of psychological assessment in addressing social behavior issues, thereby aiding in therapeutic interventions and promoting healthier social interactions. Overall, the projective hypothesis highlights the intricate link between psychological functioning and social dynamics, reinforcing the idea that social behavior is not merely situational but deeply rooted in individual psychological states.

Note: The answer correctly identifies the projective hypothesis as a framework that connects an individual's social behavior to their internal psychological state, illustrating how external interactions can reveal internal conflicts and emotions.
